

Closed Map Lemma:

Lemma: A continuous map from a compact space to a Hausdorff space is a closed map.

Pf: Suppose $f: X \rightarrow Y$ is continuous, X is compact and Y is Hausdorff. Suppose $A \subseteq X$ is closed. Since X is compact and A is closed, A is compact. Since f is continuous $f(A)$ is compact. Since Y is Hausdorff, $f(A)$ is closed.

Cor: If X is compact and Y is Hausdorff and $f: X \rightarrow Y$ is continuous and surjective then f is a quotient map.

Pf: f is continuous, surjective and closed (and hence takes saturated closed sets to closed sets.)

Cor: If X is compact and Y is Hausdorff and $f: X \rightarrow Y$ is continuous and bijective then f is a homeomorphism.

Pf: We need only establish that f^{-1} is continuous.

If $A \subseteq X$ is closed then $(f^{-1})^{-1}(A) = f(A)$ which is closed.

Cor: If X is compact and Y is Hausdorff and $f: X \rightarrow Y$ is continuous and injective then f is a top. embedding.

Pf: Note $f(X) \subseteq Y$ is Hausdorff. So $f: X \rightarrow f(X)$ is continuous and bijective from a compact space to a Hausdorff space and is hence a homeomorphism.

E.g. $[0,1]/\sim$ is homeomorphic to S^1

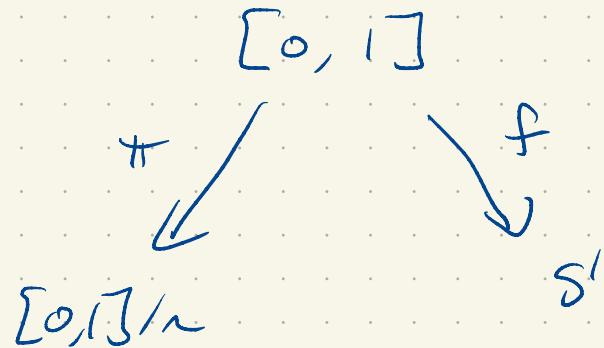

Or 1.

$$f: [0,1] \rightarrow S^1$$

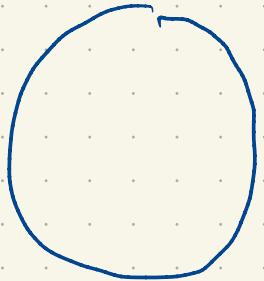

$$f(x) = e^{2\pi i x}$$

f is cts, surjective.
 $[0,1]$ is compact
 S^1 is Hausdorff.

$\Rightarrow f$ is a quotient map.

f and \sim make the same identifications.
So the quotients are homeomorphic.

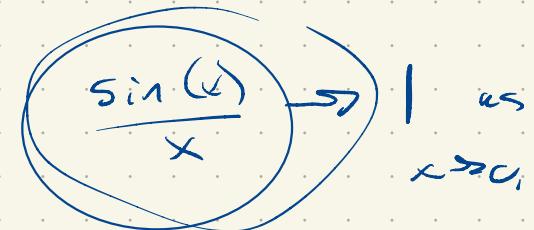

$$D^2 = \{(x,y) \in \mathbb{R}^2 : x^2 + y^2 \leq 1\}$$

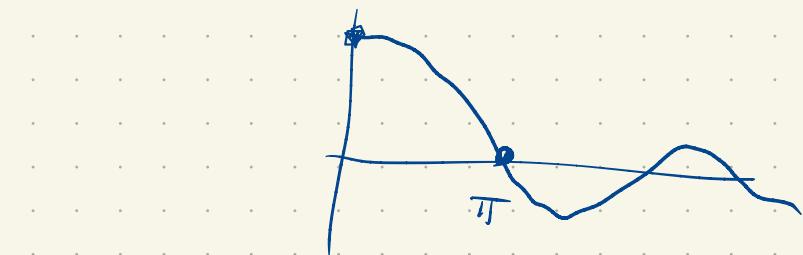

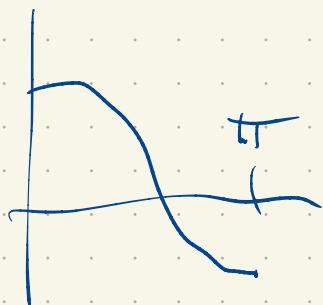

$$D^2 / \partial D^2$$

(a, b, f, g, h ∈ ∂D^2)

$$\text{Clown} \hookrightarrow D^2 / \partial D^2 \cong S^2.$$

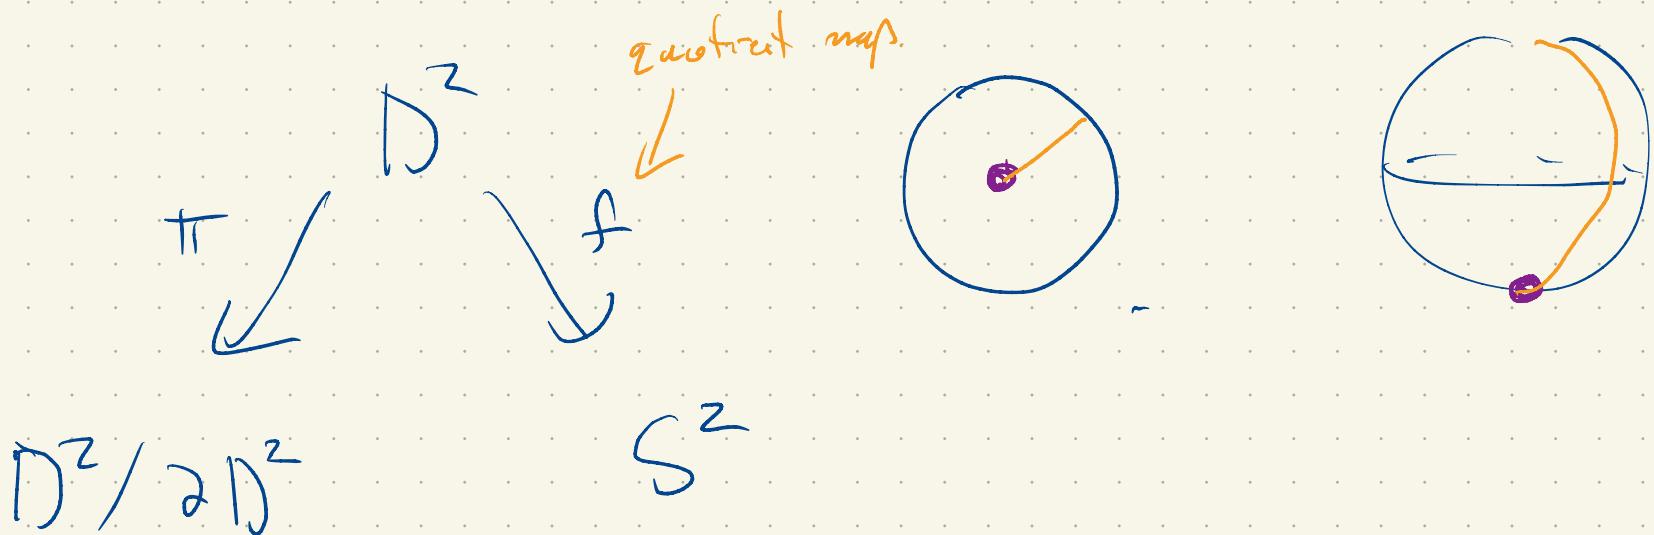

$$f(x,y) = \cos(\sqrt{x^2+y^2} \cdot \pi) \cdot (0,0,-1) + \frac{\pi \sin(\sqrt{x^2+y^2} \cdot \pi)}{\sqrt{x^2+y^2}} \cdot (x,y,0).$$

f is cts, so injective, domain is compact, codomain \hookrightarrow Henkelsch

and f makes the same identifications.

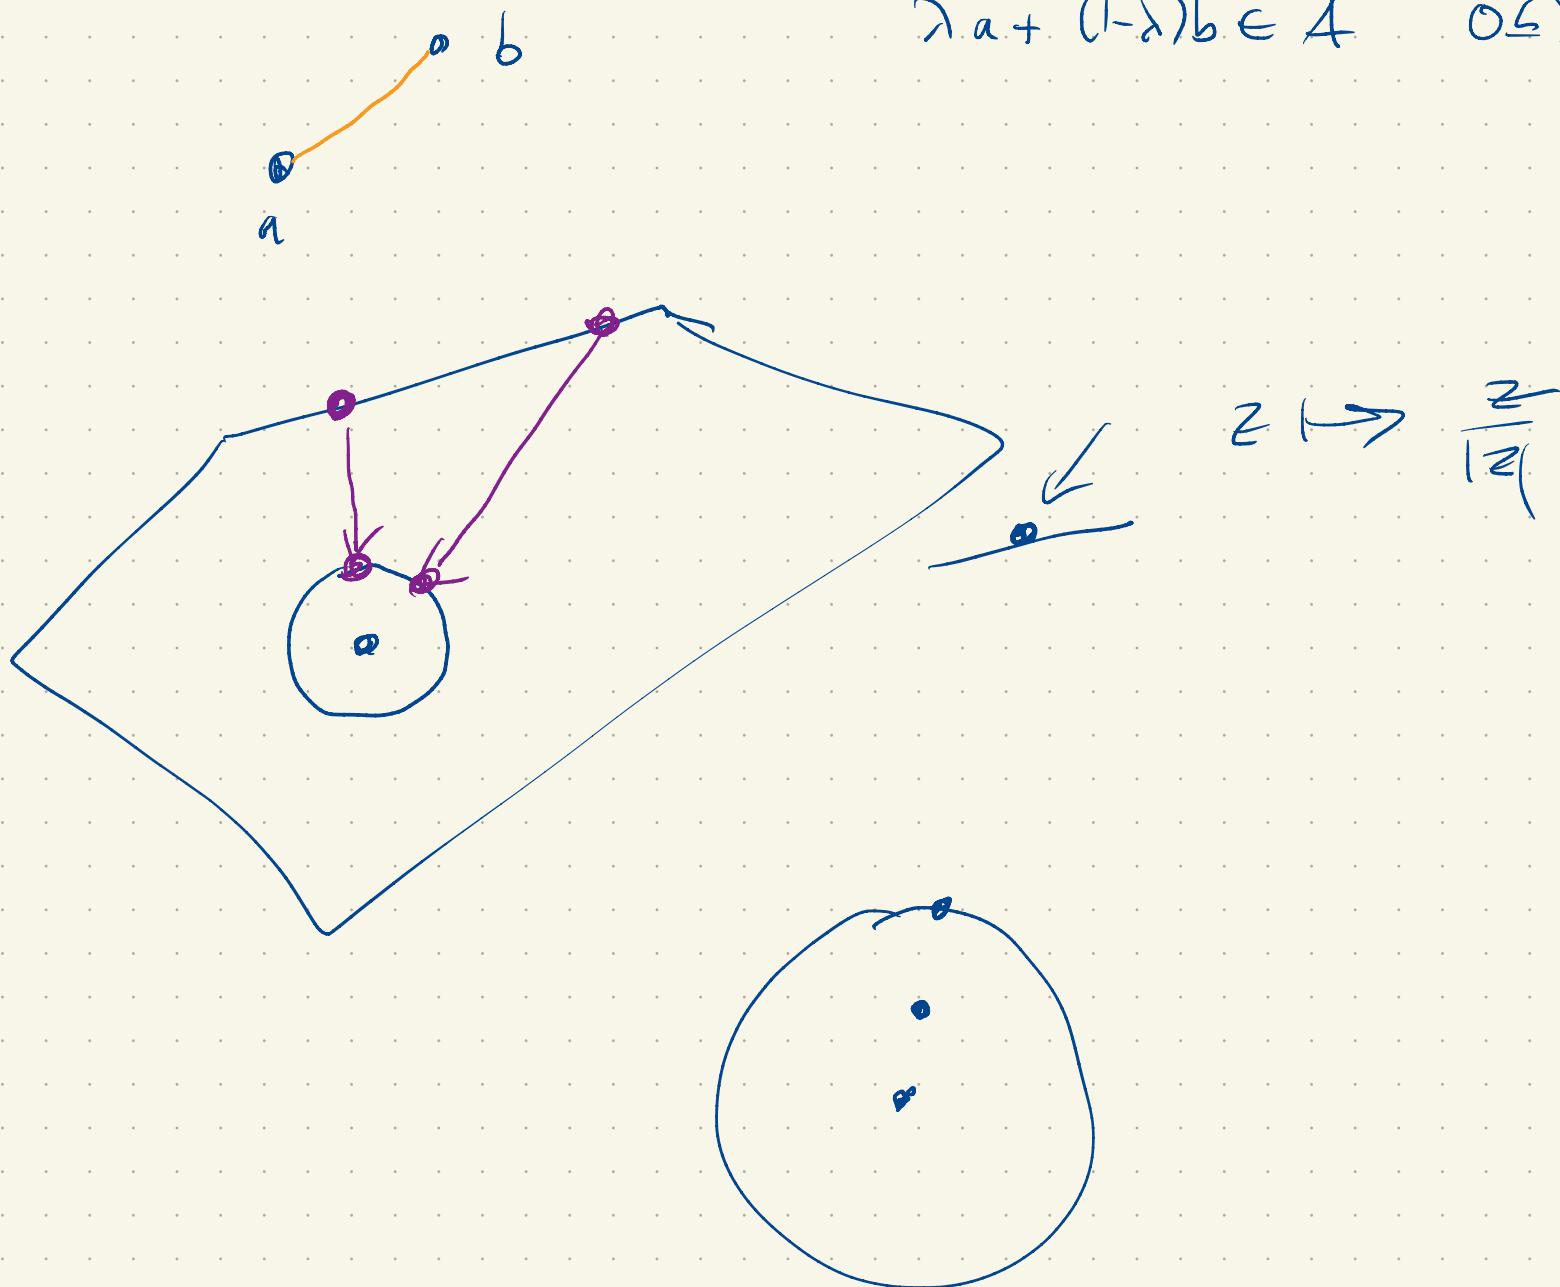

Prop: Suppose $K \subseteq \mathbb{R}^n$

- is compact
- is convex
- has nonempty interior

Then K is homeomorphic to $D^n = \{x \in \mathbb{R}^n : |x| \leq 1\}$
 by a homeomorphism taking ∂K to S^{n-1} .

$A \subseteq \mathbb{R}^n$ is convex if whenever $a, b \in A$,

$$\lambda a + (1-\lambda)b \in A \quad 0 \leq \lambda \leq 1.$$

Other notions of compactness

- 1) X is limit point compact if every infinite set in X has a limit point.
- 2) X is sequentially compact if every sequence in X has a convergent subsequence.

In general neither 1) nor 2) are equivalent to compactness.

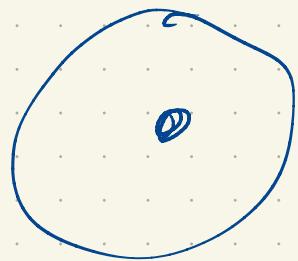

$$X = \mathbb{Z} \text{ but } 0 \in \mathbb{Z} \text{ is open \& } 0 = -0.$$

Claim: X is not compact but every nonempty set in X has a limit point.

$U_n = \{n, -n\}$ are open, no finite subcover.

If $A \subseteq \mathbb{Z}$ is nonempty then $a \in A$ for some a . Claim: $-a$ is a limit point of A .

Let U be open and containing $-a$. Then $a \in U$ as well so $U \cap A \neq \emptyset$.

Relationships

- 1) compact \Rightarrow limit point compact (always)
- 2) limit point cpt \Rightarrow sequentially cpt (1^{st} countable Hausdorff)
- 3) sequentially compact \Rightarrow compact (2^{nd} countable or metrizable)

2^{nd} countable + Hausdorff \Leftrightarrow all 3 are equivalent

metrizable \Rightarrow ↗

Prop: Compact spaces are limit point compact.

Pf: Suppose X is compact and $A \subseteq X$ has no limit points,

We'll show that A is finite. Notice, since A has no limit points it is closed. Since X is compact and A is closed, A is compact. Let $a \in A$. Then a is not a limit point of A . Hence there is an open set

U with $U \cap A = \{a\}$. Hence singletons are open in A . The cover of A by singletons admits a finite open

subcover and hence A is finite.
